

1) Test design technique

- 1) Equivalence position
- 2) Boundary value analyze

1) Equivalence position

Divided the input $\rightarrow$ equivalence position it's
Divided the input. It's output not only depends
current input all inputs divided the input

Example : The age limit is 16-80

- valid $\rightarrow$ The age limit is 16-80 is valid. age is 50
invalid $\rightarrow$ The age is 12 it's invalid below 16
invalid $\rightarrow$ The age is 85 it's invalid above 80

Input is values of age it's possibility to one
valid and two invalid statement.

Guidelines of Equivalence position

- 1) Boolean no : it given one valid and two invalid position
- 2) set of master : it given one valid and two invalid position
- 3) Series of value : it given one valid and two invalid position.

2) Boundary value anylise

Boundary value anylise have limit that are maximum and minimum. limit Boundary value anylise limits the input to output of the value

For example : age limit is 16-50

minimum is 16 and maximum is 50 it's limit

Pointers of Boundary value anylizes

valid position is 16-50
in valid position is below 16 and above 50 in
equivalence position here we use

$\min + 1$, $\min - 1$, $\min$, $\max$, $\max + 1$, $\max - 1$

Input OTP 6 digit number.

invalid valid invalid valid

1234567 345621 6123541 1155331

invalid valid invalid

$\min - 1$ $\min + 1$, $\min$, $\max + 1$
 $\max$, $\max - 1$
