

1) Explain about different testing levels and its purpose.

The different testing levels have four levels

- 1) Unit testing
- 2) Integrating testing
- 3) System Testing
- 4) Acceptance Testing

1) Unit testing

The unit testing is include condition and code it will testing include components (or) code will be testing by developer.

Who works : developer.

2) Integrating testing

After the unit testing the single components (or) code are together and testing its a Integrating testing

Who works : Tester.

3) System testing

The system testing is after the Integrating testing its will works the whole system its the testing the system its a system testing

THPL
DATE / /

Who works: Tester.

4) Acceptance testing

It's also known as user Acceptance testing (UAT) it will after the three levels of testing the final testing is a Acceptance testing is user requirement in the system product.

Who works: user end user (or) clients

2) Explain about functional and non functional testing and give atleast 2 examples from each category.

i) Functional testing

The functional testing is testing function of the system (or) device (or) product it's developed by the (or) designed by a developer it will testing tester testing the function.

- | | |
|-----------------|-----------------------|
| 1) Unit testing | 6) Regression testing |
| 2) Integration | 7) Sanity testing |
| 3) System | 8) Smoke testing |
| 4) Acceptance | |
| 5) Re-testing | |

1) unit testing

The unit testing is testing the developer developed product (or) the code (or) single component is called unit testing.

It will be tested by the developer.

2) User Acceptance testing

UAT is it testing the whole system by the user end user (or) client testing the requirement of the client.

It will be tested by the end user (or) client.

ii) non-functional testing

The non-functional testing is testing the performance of the product (or) device (or) system. Performance is scalability, responsiveness and ability.

1) performance

Performance testing is testing the scalability, responsiveness, ability and the product (or) device (or) system.

2) load testing

The load testing is check the capacity the users are using the system.

Stress testing:

The stress testing the tested the breaking
point of the system if give the
over load it check the breaking point.

(a) When performance

(ii) non-functional testing

(i) performance
